

Creating Projects

Creating a project enables you to:

- › Group files together
- › Add custom build steps
- › Include forms and resource files
- › Specify settings for running applications

Setting up a new project in Qt Creator is aided by a wizard that guides you step-by-step through the project creation process. The wizards prompt you to enter the settings needed for that particular type of project and create the necessary files for you. You can add your own custom wizards to standardize the way subprojects and classes are added to a project.

Most Qt Creator project wizards enable you to choose the build system to use for building the project: qmake, CMake, or Qbs. If you are not presented with a choice, the project is set up to use qmake.

You can use wizards also to create plain C or C++ projects that use qmake, Qbs, or CMake, but do not use the Qt library.

In addition, you can import projects as *generic projects* that do not use qmake, Qbs, or CMake. This enables you to use Qt Creator as a code editor and to fully control the steps and commands used to build the project.

You can install tools for [devices](#) as part of Qt distributions. The [kits](#) and build and run settings for the installed device types are set up automatically. However, you might need to install and configure some additional software on the devices to be able to connect to them from the development PC.

Selecting the Build System

Most Qt Creator project wizards enable you to choose the build system to use for building the project: qmake, CMake, or Qbs. If you are not presented with a choice, the project is set up to use qmake.

[qmake](#) is a cross-platform system for build automation that helps simplify the build process for development projects across different platforms. qmake automates the generation of build configurations so that only a few lines of information are needed to create each configuration. qmake is installed and configured when you install Qt. To use one of the other supported build systems, you need to set it up.

[CMake](#) is an alternative to qmake for automating the generation of build configurations. For more information, see [Setting Up CMake](#).

[Meson](#) Meson is an open source build system meant to be both extremely fast, and, even more importantly, as user friendly as possible. The main design point of Meson is that every second a developer spends writing or debugging build definitions is a second wasted. So is every second spent waiting for the build system to actually start

CMake do) and executes the commands in the low-level build graph (like make does). For more information, see [Setting Up Qbs](#).

To change the location of the project directory, and to specify settings for building and running projects, select **Edit > Preferences > Build & Run > General**. The **CMake** tab contains additional settings for CMake. You can find more settings for CMake in **Edit > Preferences > Kits > CMake** and for Qbs in **Edit > Preferences > Qbs**.

To specify build and run settings for different target platforms, select **Projects**. For more information on the options you have, see [Specifying Build Settings](#).

Using Project Wizards

In the first step, you select a template for the project. You can filter templates (1) to view only those that apply to a particular target platform.

Next, you select a location for the project and specify settings for it.

When you have completed the steps, Qt Creator automatically generates the project with required headers, source files, user interface descriptions and project files, as defined by the wizard.

For example, if you choose to create a Qt Quick application, Qt Creator generates a QML file that you can modify in the **Edit** mode.

Selecting Project Type

The following table lists the wizard templates for creating projects.

Category	Wizard Template	Purpose
Application (Qt for MCU)	MCU Support Application	Creates an application that uses a subset of Qt QML and Qt Quick Controls types (as supported by Qt for MCUs) that you can deploy, run, and debug on MCU boards. For more information, see Connecting MCUs .
Application (Qt)	Qt Widgets Application	Uses Qt Designer forms to design a Qt Widgets based user interface for the desktop and C++ to implement the application logic.

	Qt Quick Application	Creates a Qt Quick 2 application project that can contain both QML and C++ code. You can build the application and deploy it to desktop, embedded, and mobile target platforms.
Application (Qt for Python)	Empty Application	Creates a Qt for Python application that contains only the main code for a QApplication .
	Empty Window	Creates a Qt for Python application that contains an empty window.
	Window UI	Creates a Qt for Python application that contains an empty window with a widget-based UI. Preferred approach that requires you to generate a Python file from the .ui file, to import it directly into your application.
	Window UI - Dynamic load	Creates a Qt for Python application that contains an empty window with a widget-based UI.
Qt Quick Application - Empty	Creates a Python project that contains an empty Qt Quick Application.	
Library	C++ Library	A shared or static C++ library based on qmake.
	Qt Quick 2 Extension Plugin	Creates a C++ plugin that makes it possible to offer extensions that can be loaded dynamically into Qt Quick 2 applications by using the QQmlEngine class.
	Qt Creator Plugin	Creates a Qt Creator plugin.
Other Project	Qt Custom Designer Widget	Creates a custom Qt Designer widget or widget collection.
	Qt Quick UI Prototype	Creates a Qt Quick UI project with a single QML file that contains the main view. You can preview Qt Quick 2 UI projects in the QML Scene preview tool . You do not need to build them because they do not contain any C++ code. Use this template only if you are prototyping. You cannot create a full application by using this template. Qt Quick UI projects cannot be deployed to embedded or mobile target platforms. For those platforms, create a Qt Quick application instead.
	Auto Test Project	Creates a project with boilerplate code for a Qt or Google test. For more information, see Creating Tests .
	Subdirs Project	Creates a subproject that enables you to structure your qmake projects as a tree hierarchy.
	Empty qmake Project	Creates an empty qmake project that is based on qmake but does not use any default classes.
	Code Snippet	Creates a qmake project from a code snippet. When fixing bug reports that contain a code snippet, you can place the code snippet into a project to compile and check it.
Non-Qt Project Category	Plain C Application Wizard	Creates a plain C application that uses qmake, Qbs, or CMake but does not use the Qt library.
	Plain C++ Application Wizard	Creates a plain C++ application that uses qmake, Qbs, or CMake but does not use the Qt library.

Purpose

	Application (experimental)	more information, see Setting Up Nimble .
	Nimble Application (experimental)	Creates a Nimble application that uses Nimble, but does not use the Qt library. For more information, see Setting Up Nimble .
Import Project	Project from version control	Imports a project from a supported version control system, such as Bazaar, CVS, Git, Mercurial, or Subversion. For more information on how version control systems are integrated in Qt Creator, see Using Version Control Systems .
	Import as qmake or CMake Project (Limited Functionality)	Imports an existing project that does not use any of the supported build systems: qmake, Qbs, CMake, or Autotools. The template creates a project file, which enables you to use Qt Creator as a code editor and as a launcher for debugging and analysis tools. However, if you want to build the project, you might need to edit the generated project file.
	Import Existing Project	Imports an existing project that does not use any of the supported build systems: qmake, Qbs, CMake, or Autotools. This enables you to use Qt Creator as a code editor.

To create a new project, select **File > New Project** and select the type of your project. The contents of the wizard dialogs depend on the project type and the [kits](#) that you select in the **Kit Selection** dialog. Follow the instructions of the wizard.

For examples of creating different types of projects, see [Tutorials](#).

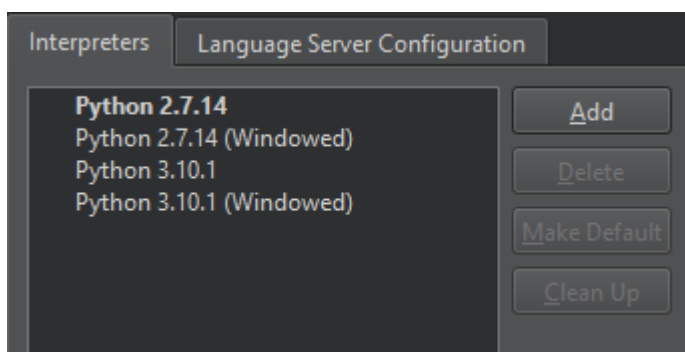

For more information about creating Qt Quick projects, see [Creating Qt Quick Projects](#).

Creating Widget-Based Qt for Python Applications

[Qt for Python](#) enables you to use Qt 6 API in Python applications. You can use the PySide6 modules to gain access to individual Qt modules, such as [Qt Core](#), [Qt GUI](#), and [Qt Widgets](#).

If you have not installed PySide6, Qt Creator prompts you to install it after the project is created. Further, it prompts you to install the [Python language server](#) that provides services such as code completion and annotations. Select **Install** to install PySide6 and the language server.

To view and manage the available Python interpreters, select **Edit > Preferences > Python > Interpreters**.

You can add and remove interpreters and clean up references to interpreters that have been uninstalled, but still appear in the list. In addition, you can set the interpreter to use by default.

The Qt for Python Application wizards generate a `.pyproject` file that lists the files in the Python project and a `.py` file that contains some boilerplate code. In addition, the widget based UI wizard creates a `.ui` file that contains a Qt Designer form, and the Qt Quick Application wizard creates a `.qml` file that contains Qt Quick

files. You can still open and use `.pyqtc` files, but we recommend that you choose `.pyproject` files for new projects.

The **Window UI** wizard enables you to create a Python project that contains the source file for a class. Specify the PySide version, class name, base class, and source file for the class.

The wizard adds the imports to the source file to provide access to the `QApplication`, the base class you selected in the Qt Widgets module, and Qt UI tools:

```
import sys

from PySide6.QtWidgets import QApplication, QWidget
```

Note: It is important that you first create the Python code from your UI form. In PySide6, you can do this by executing `pyside6-uic form.ui -o ui_form.py` on a terminal. This enables you to import the class that represents your UI from that Python file.

Once you generate the Python code from the UI file, you can import the class:

```
from ui_form import Ui_Widget
```

The wizard also adds a main class with the specified name that inherits from the specified base class:

```
def __init__(self, parent=None):
    super().__init__(parent)
```

The following lines in the main class instantiate the generated Python class from your UI file, and set up the interface for the current class.

```
self.ui = Ui_Widget()
self.ui.setupUi(self)
```

Note: UI elements of the new class can be accessed as member variables. For example, if you have a button called *button1*, you can interact with it using `self.ui.button1`.

Next, the wizard adds a main function, where it creates a `QApplication` instance. As Qt can receive arguments from the command line, you can pass any arguments to the `QApplication` object. Usually, you do not need to pass any arguments, and you can use the following approach:

```
if __name__ == "__main__":
    app = QApplication(sys.argv)
```

Next, the wizard instantiates the `MainWindow` class and shows it:

```
widget = Widget()
widget.show()
...
```

Finally, the wizard calls the `app.exec()` method to enter the Qt main loop and start executing the Qt code:

```
sys.exit(app.exec())
```

You can now modify the boilerplate code in the Edit mode to develop your Python application. Select **REPL** on the toolbar to start the `Python interactive shell`. To start the shell and import the current file as a module, select **REPL Import File**. To also import all functions from the file, select **REPL Import ***.

Always regenerate the Python code after modifying a UI file.

Open the `.ui` file in the **Design** mode to create a widget-based UI in Qt Designer.

The **Window** wizard adds similar code to the source file, without the UI bits.

The **Empty** wizard adds similar code to the source file, but it does not add any classes, so you need to add and instantiate them yourself.

For examples of creating Qt for Python applications, see [Qt for Python Examples and Tutorials](#).

Specifying Project Contents

A project can contain files that should be:

- › Compiled or otherwise handled by the build
- › Installed
- › Not installed, but included in a source package created with `make dist`
- › Not installed, nor be part of a source package, but still be known to Qt Creator

Qt Creator displays all files that are declared to be part of the project by the project files in the [Projects](#) view. The files are sorted into categories by file type (.cpp, .h, .qrc, and so on). To display additional files, edit the project file. Alternatively, you can see all the files in a project directory in the [File System](#) view.

Declaring files as a part of the project also makes them visible to the [locator](#) and [project-wide search](#).

CMake Projects

When using CMake, you can specify additional files for a project by either adding them as sources or installing them.

In the CMakeLists.txt file, define the files as values of the [target_sources](#) command using the `PRIVATE` property, for example.

You can prevent CMake from handling some files, such as a .cpp file that should not be compiled. Use the [set_property](#) command and the [HEADER_FILE_ONLY](#) property to specify such files. For example:

```
set_property(SOURCE "${files}" PROPERTY HEADER_FILE_ONLY ON)
```

Alternatively, to install the files, use the [install](#) command with the `FILES` or `DIRECTORY` property.

qmake Projects

Use the following variables in the .pro file:

- › `SOURCES` and `HEADERS` for files to compile
- › `INSTALLS` for files to install
- › `DISTFILES` for files to include in a source package
- › `OTHER_FILES` for files to manage with Qt Creator without installing them or including them in source packages

For example, the following value includes text files in the source package:

```
DISTFILES += *.txt
```

In addition to Qt libraries, you can link your application to other libraries, such as system libraries or your own libraries. Further, your own libraries might link to other libraries. To be able to compile your project, you must add the libraries to your project. This also enables code completion and syntax highlighting for the libraries. The procedure of adding a library to a project depends on the build system that you use.

CMake Projects

You can add CMakeLists.txt files to any project by using the `add_subdirectory` command. The files can define complete projects that are included into the top-level project or any other CMake commands.

qmake Projects

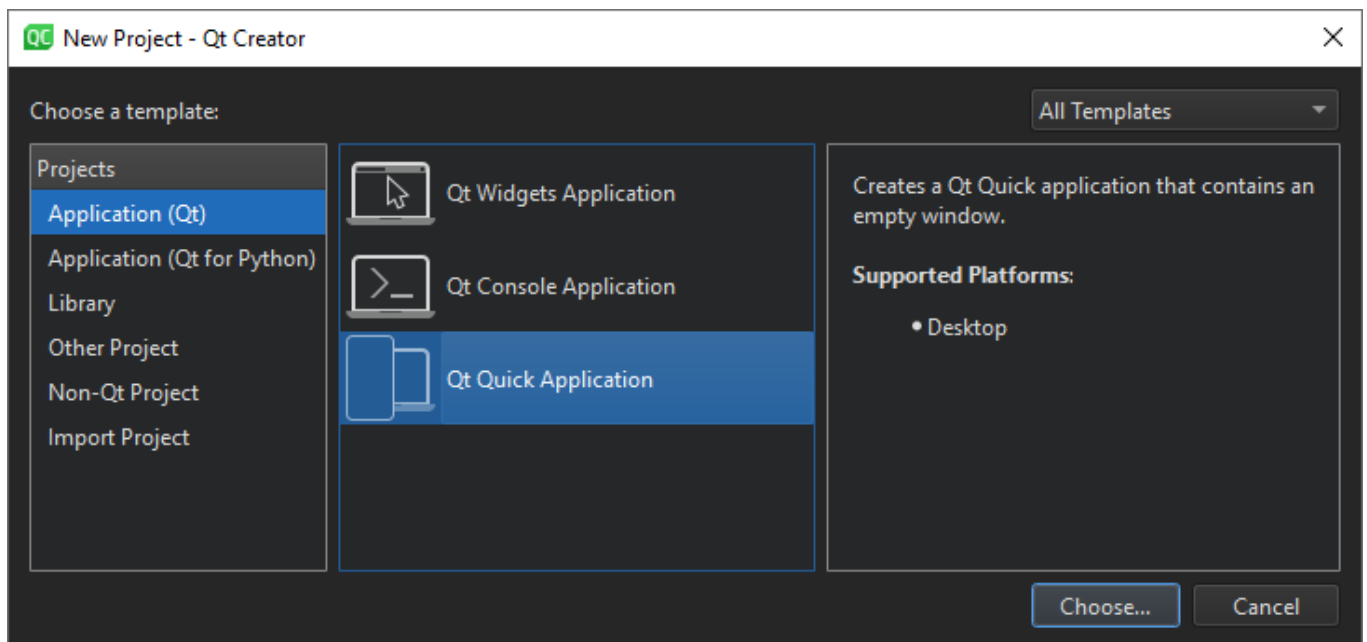

When you create a new project and select qmake as the build system, you can add it to another project as a subproject in the **Project Management** dialog. However, the root project must specify that qmake uses the `subdirs` template to build the project.

To create a root project, select **File > New Project > Other Project > Subdirs Project > Choose**.

On the **Summary** page, select **Finish & Add Subproject** to create the root project and to add another project, such as a C++ library.

The wizard creates a project file (.pro) that defines a `subdirs` template and the subproject that you add as a value of the `SUBDIRS` variable. It also adds all the necessary files for the subproject.

To create more subprojects, right-click the project name in the **Projects** view to open the context menu, and select **New Subproject**. Follow the steps in the **New Subproject** wizard to create a subproject.

To add an existing project as a subproject, select **Add Existing Projects** in the context menu. In the file browser dialog, locate your subproject.

To remove subprojects, right-click the project name in the **Projects** view, and select **Remove Subproject** in the context menu.

To specify dependencies, use the **Add Library** wizard. For more information, see [Adding Libraries to Projects](#).

Binding Keyboard Shortcuts to Wizards

Keyboard shortcuts for wizards can be set in **Edit > Preferences > Environment > Keyboard > Wizard**. All wizard actions start with **Impl** there.
